

## 1 Maximum Likelihood Estimator

Three properties of maximum likelihood estimator:

1.  $\theta_{ML}$  is consistent.  $\theta_{ML} \rightarrow \theta_0$  when  $n \rightarrow \infty$ .
2.  $\theta_{ML}$  is asymptotically normal.  $\sqrt{n}(\theta_{ML} - \theta_0) \sim \mathcal{N}(0, I_n(\theta_0))$  when  $n \rightarrow \infty$  and  $I_n(\theta_0)$  is the fisher information.
3.  $\theta_{ML}$  is asymptotically efficient.  $\theta_{ML}$  minimizes  $\mathbb{E}(\theta - \theta_0)^2$  when  $n \rightarrow \infty$  because the asymptotic variance equals the Rao-Cramer bound (MLE is asymptotically unbiased). Note: when  $n$  is finite,  $\theta_{ML}$  is not necessarily efficient, e.g., Stein estimator is universally more efficient for single sample.

Rao-Cramer bound: for any unbiased estimator  $\hat{\theta}$  of  $\theta_0$ ,  $\mathbb{E}(\hat{\theta} - \theta_0)^2 \geq 1/I_n(\theta_0)$ , where  $I_n(\theta) = -\mathbb{E}(\frac{\partial^2}{\partial \theta^2} \log f(X; \theta) | \theta) = \mathbb{E}(\frac{\partial}{\partial \theta} \log f(X; \theta) | \theta)^2$  is the fisher information.

Sketch of Proof: define  $\Lambda = \frac{\partial \log P(X; \theta)}{\partial \theta}$ . Cauchy-Schwarz says  $\text{Cov}^2(\Lambda, \hat{\theta}) \leq \text{Var}(\Lambda) \text{Var}(\hat{\theta}) = \mathbb{E}(\Lambda^2) \text{Var}(\hat{\theta})$  because  $\mathbb{E}\Lambda = 0$ . Note that  $\text{Cov}(\Lambda, \hat{\theta}) = \mathbb{E}(\Lambda \hat{\theta}) = \int_X \hat{\theta}(x) \frac{\partial}{\partial \theta} f(x; \theta) dx = \frac{\partial}{\partial \theta} \int_X \hat{\theta}(x) f(x; \theta) dx = \frac{\partial}{\partial \theta} \mathbb{E}\hat{\theta} = 1$ . Therefore,  $\text{Var}(\hat{\theta}) \geq 1/\mathbb{E}(\Lambda^2)$ .

However, when the dimension of problem goes to infinity while keeping the data-dim ratio fixed, MLE is biased and the  $p$ -values are unreliable.

## 2 Regression

### Bias-Variance trade-off

Let  $D$  be the training dataset and  $\hat{f}$  be the predictive function.  $\mathbb{E}_D \mathbb{E}_{Y|X} (\hat{f}(X) - Y)^2 = \mathbb{E}_D \mathbb{E}_{Y|X} [(\hat{f}(X) - \mathbb{E}_{Y|X} Y)^2 + (\mathbb{E}_{Y|X} Y - Y)^2] = \mathbb{E}_D (\hat{f}(X) - \mathbb{E}(Y | X))^2 + \mathbb{E}_D (\mathbb{E}(Y | X) - Y)^2 = \mathbb{E}_D (\hat{f}(x) - \mathbb{E}_D \hat{f}(x))^2 + (\mathbb{E}_D \hat{f}(x) - \mathbb{E}(Y | X))^2 + \mathbb{E}_D (\mathbb{E}(Y | X) - Y)^2$ . It means that expected square error (training) = variance of prediction + squared bias + variance of noise. The optimal trade-off is achieved by avoiding under-fitting (large bias) and over-fitting (large variance). Note that here the variance of output is computed by refitting the regressor on a new dataset.

### Regularization

Ridge and Lasso can be viewed as MAP (maximum a posterior) estimation. A Gaussian prior on  $\beta$  is equivalent to Ridge and a Laplacian prior is equivalent to Lasso. Using

SVD, we get Ridge has built-in model selection:  $X\beta^{\text{Ridge}} = \sum_{j=1}^d [d_j^2/(d_j^2 + \lambda)] u_j u_j^T Y$  (each  $u_j u_j^T Y$  can be viewed as a model). Lasso has more sparse estimations because the gradient of regularization does not shrink as in the case of Ridge.

## 3 BLR and GP

### Bayesian Linear Regression

$Y = X\beta + \epsilon$ ,  $\epsilon \sim \mathcal{N}(0, \sigma^2)$  and a prior  $\beta \sim \mathcal{N}(0, \Lambda^{-1})$ . By Bayesian,  $\beta | X, Y \sim \mathcal{N}(\mu_\beta, \Sigma_\beta)$ , where  $\mu_\beta = (X^T X + \sigma^2 \Lambda)^{-1} X^T Y$  and  $\Sigma_\beta = \sigma^2 (X^T X + \sigma^2 \Lambda)^{-1}$ . MAP estimation of this prior (i.e.,  $\mu_\beta$ ) is equivalent to Ridge regression given  $\Lambda = \lambda I$  and  $\sigma = 1$ .

When  $\Lambda = \lambda I$ , under the prior,  $Y \sim \mathcal{N}(0, \frac{1}{\lambda} X^T X + \sigma^2 I)$ . Therefore,  $\text{Cov}(y_i, y_j) = \frac{1}{\lambda} x_i^T x_j$ . It means a prior that closer samples is more similar, i.e.,  $\text{Cov}(y_i, y_j)$  is large when  $x_i^T x_j$  is large. The kernel  $X^T \Lambda^{-1} X$  is thus called linear kernel. When a general kernel is used, Gaussian Process appears.

### Gaussian Process

#### Kernel Function

A function is a kernel iff  $k(x, x') = k(x', x)$  (symmetry) and  $\int_{\Omega} k(x, x') f(x) f(x') dx dx' \geq 0$  for any  $f \in L_2$  and  $\Omega \in \mathcal{R}^d$  (semi-positiveness in continuous case) or  $K(X)$  is a valid covariance matrix for any  $X$  (semi-positiveness in discrete case). The latter is equivalent to either (1)  $\sum_{i,j} a_i a_j K(x_i, x_j) \geq 0$  for any  $a_i, j$  and  $k_{i,j}$ , or (2)  $k(x, x') = \phi(x)^T \phi(x')$  for some  $\phi$ .

Assume  $k_{1,2}$  are valid kernels, then the following are valid kernels:

1.  $k(x, x') = k_1(x, x') + k_2(x, x')$ .
2.  $k(x, x') = k_1(x, x') \cdot k_2(x, x')$ . Proof: let  $V \sim \mathcal{N}(0, K_1)$ ,  $W \sim \mathcal{N}(0, K_2)$  and is independent to  $V$ , then  $\text{Cov}(V_i W_i, V_j W_j) = \text{Cov}(V_i, V_j) \text{Cov}(W_i, W_j) = k_1 \cdot k_2(x_i, x_j)$ .
3.  $k(x, x') = c k_1(x, x')$  for constant  $c > 0$ .
4.  $k(x, x') = f(k_1(x, x'))$  if  $f$  is a polynomial with positive coefficients or the exp. Proof: polynomial can be proved by applying the product, positive scaling and addition. Exp can be proved by taking limit on the polynomial.
5.  $k(x, x') = f(x) k_1(x, x') f(x')$ .
6.  $k(x, x') = k_1(\phi(x), \phi(x'))$  for any function  $\phi$ .

Example: RBF kernel  $k(x, y) = \exp(-\frac{1}{2\sigma^2} \|x - y\|^2) = \exp(-\frac{1}{2\sigma^2} \|x\|^2) \exp(\frac{1}{\sigma^2} x^T y) \exp(-\frac{1}{2\sigma^2} \|y\|^2)$

is valid. Since  $x^T y$  is the linear kernel and thus  $\exp(\frac{1}{\sigma^2} x^T y)$  is a valid kernel, let  $f(x) = \exp(-\frac{1}{2\sigma^2} \|x\|^2)$ , we get the RBF function equals  $f(x)k(x, y)f(y)$ , which is a valid kernel.

### Mercer's Theorem

Assume  $k(x, x')$  is a valid kernel. Then there exists an orthogonal basis  $e_i$  and  $\lambda_i \geq 0$ , s.t.  $k(x, x') = \sum_i \lambda_i e_i(x) e_i(x')$ .

### Conditional Gaussian

$\mathbb{E}(y_2 | y_1) = \mu_2 + \Sigma_{21} \Sigma_{11}^{-1} (y_1 - \mu_1)$ ,  $\text{Var}(y_2 | y_1) = \Sigma_{22} - \Sigma_{21} \Sigma_{11}^{-1} \Sigma_{12}$ .

## 4 Linear Methods for Classification

### Concept Comparison

1. Probabilistic Generative, modeling  $p(x, y)$ : (1) can create new samples, (2) outlier detection, (3) probability for prediction, (4) high computational cost and (5) high bias.
2. Probabilistic Discriminative, modeling  $p(y | x)$ : (1) probability for prediction, (2) medium computational cost and (3) medium bias.
3. Discriminative, modeling  $y = f(x)$ : (1) no probability for prediction, (2) low computational cost and (3) low bias.

### Infer $p(x, y)$ for classification problems

Use  $p(x, y) = p(y)p(x | y)$ . Since  $y$  has finite states, model  $p(y)$  and  $p(x | y)$  for different  $y$ . The modeling requires to (1) guess a distribution family and (2) infer parameters by MLE.

### Compute $p(y | x)$ by discriminant analysis (DA)

#### Linear DA

Goal: classify a sample into two Gaussian distribution with  $\Sigma_0 = \Sigma_1$ . After calculation,  $p(y = 1 | x) = 1/(1 + \exp(-\log \frac{p(x|y=1)p(y=1)}{p(x|y=0)p(y=0)})) = 1/(1 + \exp(w_1^T x + w_0))$  since the quadratic term is eliminated due to  $\Sigma_0 = \Sigma_1$ .

#### Quadratic DA

Goal: classify a sample into two Gaussian distribution with  $\Sigma_0 \neq \Sigma_1$ . After calculation,  $p(y = 1 | x) = 1/(1 + \exp(x^T W x + w_1^T x + w_0))$ .

### Optimization Methods

#### Optimal Learning Rate for Gradient Descent

Goal: find  $\eta^* = \text{argmin}_{\eta} L(w^k - \eta \cdot \nabla L(w^k))$ .

By Taylor expansion of  $L(w^{k+1})$  at  $w^k$  and solve for the optimal  $\eta$ , we get  $\eta^* = \frac{\|\nabla L(w^k)\|^2}{\nabla L(w^k)^T H_L(w^k) \nabla L(w^k)}$ .

However, naive gradient descent has two

weaknesses: (1) it often has a zig-zag behavior, especially in a very narrow, long and slightly downward valley; (2) the gradient update is small near the stationary point. This can be mitigated by adding a momentum term in the update:  $w^{k+1} = w^k - \eta \nabla L(w^k) + \mu^k (w^k - w^{k-1})$  which speeds the update towards the “common” direction.

### Newton's Method

Taylor-expand  $L(w)$  at  $w_k$  to derive the optimal  $w^{k+1}$ :  $L(w) \approx L(w_k) + (w - w^k)^T \nabla L(w^k) + \frac{1}{2} (w - w^k)^T H_L(w^k) (w - w^k) \Rightarrow w^{k+1} = w^k - H_L^{-1}(w^k) \nabla L(w^k)$ .

Pros: (1) better updates compared to GD since it uses the second Taylor term and (2) does not require learning rate.

Cons: requires  $H_L^{-1}$  which is expensive.

### Bayesian Method

In most cases, the posterior is intractable. Use approximation of posterior instead.

### Laplacian Method

Idea: approximate posterior near the MAP estimation with a Gaussian distribution.  $p(w | X, Y) \propto p(w, X, Y) \propto \exp(-R(w))$ , where  $R(w) = -\log p(w, X, Y)$ . Let  $w^* = \text{argmin} R(w)$  be the MAP estimation and Taylor-expand  $R(w)$  at  $w^*$ :  $R(w) \approx R(w^*) + \frac{1}{2} (w - w^*)^T H_R(w^*) (w - w^*)$ . Therefore,  $p(w | X, Y) \propto \exp(-R(w^*) - \frac{1}{2} (w - w^*)^T H_R(w^*) (w - w^*))$  and thus  $(w | X, Y) \sim \mathcal{N}(w^*, H_R^{-1}(w^*))$ .

### AIC & BIC

- Define  $\text{BIC} = k \log N - 2 \log \hat{L}$ , where  $k$  is #parameters and  $\hat{L}$  is the likelihood  $p(x | w^*)$ . A lower BIC means a better model.
- Define  $\text{AIC} = 2k - 2 \log \hat{L}$ . A lower AIC means a better model.

### LDA by loss minimization

#### Perceptron

Goal: for  $y_i \in \{0, 1\}$ , find  $w$ , s.t.  $y_i w^T x_i > 0$  for any  $i$ . The classification function is  $c(x) = \text{sgn}(w^T x)$ .

$L(y, c(x)) = 0$  if  $y w^T x > 0$  and  $L(y, c(x)) = -y w^T x$  o.w. By gradient descent, the Perceptron is guaranteed to converge if (1) the data is linearly separable, (2) learning rate  $\eta(k) > 0$ , (3)  $\sum_k \eta(k) \rightarrow +\infty$  and (4)  $(\sum_k \eta(k)^2) / (\sum_k \eta(k))^2 \rightarrow 0$ . However, there exists multiple solutions if the data is linearly separable.

## Fisher's LDA

Idea: project the two distribution into one dimension and maximize the ratio of the variance between the classes and the variance within the classes, i.e.,  $\max(w^T u_1 - w^T u_0)^2 / (w^T S w)$ , where  $S = \Sigma_0 + \Sigma_1$ . Let gradient be zero and solve for  $w^*$ , we get  $w^* \propto S^{-1}(u_1 - u_0)$ .

We first compute  $w^*$  and fit distributions of the two-class projection. Then apply Bayesian decision theory to make classification.

## 5 Convex Optimization

Definition: the objective is convex and the feasible set is convex. The standard form is to minimize a convex function ( $f(w)$  for convex  $f$ ) under affine equality constraint ( $g_i(w) = 0$  for affine  $g_i$ ) and convex non-positive constraint ( $h_i(w) \leq 0$  for convex  $h_i$ ).

### How to Solve

- (1) Define Lagrangian:  $L(w, \lambda, \alpha) = f(w) + \sum_i \lambda_i g_i(w) + \sum_j \alpha_j h_j(w)$  and  $\alpha_j \geq 0$ .
- (2) Check whether strong duality holds using Slater's condition (sufficient but not necessary): there is a strictly feasible point, i.e.,  $\exists w_0$ , s.t.  $g_i(w_0) = 0$  and  $h_i(w_0) < 0$ .
- (3) Solve for  $dL(w) = 0$ ,  $g_i(w) = 0$ ,  $\alpha \geq 0$ ,  $h_j(w) \leq 0$  and  $\alpha_j h_j(w) = 0$  (complementary slackness).
- (4) Weak duality always holds and when Slater's condition holds it equals  $\min_w f(w)$ : solve  $\max_{\lambda, \alpha} \Theta(\lambda, \alpha)$  s.t.  $\alpha \geq 0$ , where  $\Theta(\lambda, \alpha) = \min_w L(w, \lambda, \alpha)$ . The optimal in the weak duality is a lower bound for  $\min_w f(w)$  since  $\Theta(\lambda, \alpha) \leq \min_w f(w)$  for any  $\lambda$  and  $\alpha$ .

## 6 Support Vector Machine

### Hard-Margin SVM

The optimization form is to minimize  $\frac{1}{2} \|w\|^2$ , s.t.  $y_i(w^T x_i + w_0) \geq 1$  ( $y_i \in \{-1, 1\}$ ). It is convex and the Slater's condition holds under the assumption of linear separability.

By solving  $\min_{w, w_0} L(w, w_0, \alpha)$ , the duality form is  $\max_{\alpha} -\frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j x_i^T x_j + \sum_i \alpha_i$ , s.t.  $\alpha_i \geq 0$ ,  $\sum_i \alpha_i y_i = 0$ .  $w^* = \sum_{i \in \text{support}} \alpha_i^* y_i x_i$ .

### Soft-Margin SVM & Kernel SVM

When the data is not linearly separable, one solution is to add slack variables:  $\min_{\xi, w, w_0} \frac{1}{2} \|w\|^2 + C \sum_i \xi_i$ , s.t.  $y_i(w^T x_i + w_0) \geq 1 - \xi_i$  and  $\xi_i \geq 0$ . Note: when the data is linearly separable, soft-margin does not necessarily produce the same cut-plane as the hard-margin SVM, especially when the margin is small due to few support vectors. When  $C \rightarrow \infty$ , it becomes hard-margin SVM.

The only difference in the dual form is that we need an extra condition  $0 \leq \alpha \leq C$ .  $\xi_i^* = \max(0, 1 - y_i(w^{*T} x_i + w_0))$ . Another solution, Kernel SVM, is to use  $K(x_i, x_j) = \phi(x_i)^T \phi(x_j)$  to replace  $x_i^T x_j$ .

### Multi-class SVM

Idea: use  $M := \text{\#class}$  hyperplanes and maximize the generalized margin:  $\min \sum_{i=1}^M w_i^T w_i$  s.t.  $w_{y_i}^T x_i + w_{y_i,0} - \max_{y \neq y_i} w_y^T x_i + w_{y,0} \geq 1$ .

### Structural SVM

Goal: predict a structured output label, e.g., parsing trees.

Difficulty of predicting structures:

- (1) Compact representation of output space. Sol: use a score function and feature map  $\hat{y} = \text{argmax}_y w^T \Psi(x, y)$ .
- (2) Efficient prediction (cannot use brute-force search to find argmax). Sol: assume structures such as decomposable output spaces.
- (3) Define prediction error (cannot use 0/1 errors). Sol: use a loss function  $\Delta(y, \hat{y})$ .
- (4) Efficient training (cannot evaluate all constraints). Sol: iteratively add new constraints to the training.

$$\min_{w, \xi \geq 0} \frac{1}{2} w^T w + C \sum_{i=1}^n \xi_i, \text{ s.t. } w^T \Psi(z_i, y_i) - \max_{z \neq z_i} [\Delta(z, z_i) + w^T \Psi(z, y_i)] \geq -\xi_i, \forall y_i \in \mathcal{Y}.$$

## 7 Ensemble

### Random Forest

Random feature selection induces regulation.

### Adaboost

Classifier weight  $\alpha_t = \frac{1}{\text{weighted err}_t} - 1$ . Sample weight  $w_{t+1} = \alpha_t w_t$  for mislabeled samples, o.w. unchanged.

Adaboost has following properties:

- (1) It minimizes exponential loss forwardly.
- (2) It trains max-margin classifiers.
- (3) It, as well as Random Forest, is spiky self-averaging interpolators, which localize the effect of noise.
- (4) It falls into the double descent regime: over-parameterized models can have better generalization.

## 8 Generative Models

Variational Autoencoder: use approximated probability to model  $p(z|x)$  and the  $p(x|z)$ .

- Pro: can be used as feature representation.
- Con: generated images are blurrier and relatively low compared to GAN.

Generative Adversarial Network: use 2-player game to sample from  $p(x)$ .

- Pro: SOTA.

- Con: (1) unstable, (2) potential mode collapse and (3) cannot solve  $p(x)$ .

## 9 Non-parametric Bayesian Method

### Property of NIW

Normal Inverse Wishart distribution  $\mu, \Sigma \sim \text{NIW}(\mathbf{m}_0, k_0, v_0, S_0)$  is the conjugate prior of multivariate Gaussian distribution. It has the following properties:

- $\mu | m_0, k_0, \Sigma \sim \mathcal{N}(m_0, \frac{1}{k_0} \Sigma)$ .
- $\Sigma | v_0, S_0 \sim \mathcal{W}^{-1}(S_0, v_0)$ , where  $\mathcal{W}^{-1}$  is the inverse Wishart distribution.
- Assume  $X \sim \mathcal{N}(\mu, \Sigma)$ . Then  $\mu, \Sigma | X \sim \text{NIW}(\mathbf{m}_p, k_p, v_p, S_p)$ , where  $\mathbf{m}_p = \frac{k_0}{k_0+N} \mathbf{m}_0 + \frac{N}{k_0+N} \bar{X}$ ,  $k_p = k_0 + N$ ,  $v_p = v_0 + N$  and  $S_p = S_0 + S_{\bar{X}} + k_0 \mathbf{m}_0 \mathbf{m}_0^T - k_p \mathbf{m}_p \mathbf{m}_p^T$  ( $S_{\bar{X}}$  is the sample covariance of  $X$ ). That is, the posterior only depends on sample mean and covariance.

### Bayesian Inference for Multivariate Gaussian with Semi-Conjugate Prior

Goal: estimate  $\mu, \Sigma$  given the NIW prior and  $X$ . The problem is  $\mu, \Sigma | X$  is hard to sample from while we can easily sample from  $\mu | \Sigma, X \sim \mathcal{N}(m_p, \frac{1}{k_p} \Sigma)$  and  $\Sigma | X \sim \mathcal{W}^{-1}(S_p, v_p)$ . Apply

Gibbs sampling, we use  $\mu_t \xleftarrow{\$} p(\mu | \Sigma_{t-1}, X)$  and  $\Sigma_t \xleftarrow{\$} p(\Sigma | \mu_{t-1}, X)$ .

### BI for Gaussian Mixture Model

Setting:  $\mu$  and  $\Sigma$  follows the same prior, and we add a "class index" variable  $z_i \sim \text{Cat}(\pi)$ , where  $\pi \sim \text{Dir}(\alpha)$ .  $\text{Dir}(\alpha)$  is the Dirichlet distribution which generates  $\pi$  satisfying  $\sum_{i=1}^k \pi_i = 1$  and is the conjugate prior for categorical distribution. Use Gibbs sampling, we can estimate  $\mu, \Sigma, z_i, \pi$ . Note that here since #classes is predetermined,  $\alpha$  is actually not needed.

Concept here: d-separation, used to convert connectedness in the causal graph to conditional independence. If two variables are d-separated, then they are independent; o.w. not guaranteed to be dependent. Two variables are d-separated if all *undirected* paths between them are inactive. If any triple  $(x, y, z)$  in a path is of the following inactive form, then the whole path is inactive: (1)  $x - y - z$  is not of the form  $x \rightarrow y \leftarrow z \wedge y$  is observed (conditioned); (2)  $x - y - z$  is of the form  $x \rightarrow y \leftarrow z \wedge$  no descendants of  $y$  ( $y$  included) is observed.

## BI for Non-Parametric GMM

GEM distribution is a special case of Dirichlet process which only takes one parameter (indicating no difference between classes). It gives a probability  $\pi$  of a categorical distribution with infinite #classes. We sample  $\pi_i$  sequentially (stick-breaking):  $\beta_i \sim \beta(1, \alpha)$ ,  $\pi_1 = \beta_1$  and  $\pi_t = \prod_{j < t} (1 - \beta_j) \beta_t$ . We can use GEM distribution to adaptively learn the required #clusters. Another approach is to directly model  $z_i$  instead of drawing  $z_i$  from  $\text{Cat}(\pi)$  by Chinese Restaurant Process. The CRP( $\alpha$ ) decides for every incoming sample  $X_n$  which cluster  $z_n$  it belongs to by  $p(z_n = k) = \frac{\#\{\text{samples in cluster } k\}}{(\alpha + n - 1)}$  and  $p(z_n = k) = \alpha / (\alpha + n - 1)$  for the left most cluster that contains no samples (a new cluster).  $\alpha$  is the concentration parameter that defines how likely a sample belongs to an old cluster. In expectation, #clusters =  $O(\alpha \log N)$ . The order of the samples incoming does not change the distribution of the partition.

Note that  $z_n$  in CRP only depends on  $z_{j < n}$ . Therefore, we can use collapsed Gibbs sampling for  $z^t$ :  $z^t \sim p(z | z^{t-1}, X)$ .

## 10 PAC Learning

Definitions:

- A learning algorithm  $\mathcal{A}$  can learn  $c \in \mathcal{C}$  if there is a  $\text{poly}(\dots)$ , s.t. for (1) any distribution  $\mathcal{D}$  on  $\mathcal{X}$  and (2)  $\forall 0 < \epsilon < \frac{1}{2}, 0 < \delta < \frac{1}{2}$ ,  $\mathcal{A}$  outputs  $\hat{c} \in \mathcal{H}$  given a sample of size at least  $\text{poly}(\frac{1}{\epsilon}, \frac{1}{\delta}, \text{size}(c))$  such that  $P(\mathcal{R}(\hat{c}) - \inf_{c \in \mathcal{C}} \mathcal{R}(c) \leq \epsilon) \geq 1 - \delta$ .
- $\mathcal{A}$  is called an efficient PAC algorithm if it runs in polynomial of  $\frac{1}{\epsilon}$  and  $\frac{1}{\delta}$ .
- $\mathcal{C}$  is (efficiently) PAC-learnable from  $\mathcal{H}$  if there is an algorithm  $\mathcal{A}$  that (efficiently) learns  $\mathcal{C}$  from  $\mathcal{H}$ .

VC inequality:

- For an ERM  $\hat{c}_n^*$ ,  $P(\mathcal{R}(\hat{c}_n^*) - \inf_{c \in \mathcal{C}} \mathcal{R}(c) > \epsilon) \leq 2|\mathcal{C}| \exp\left(-\frac{n\epsilon^2}{2}\right)$ .
- Finite VC-dimension means PAC-learnable.

## A Appendix

$$\frac{\partial}{\partial \Sigma} \log |\Sigma| = \Sigma^{-T}.$$

$$\frac{\partial \vec{u}^T \vec{v}}{\partial x} = \frac{\partial \vec{u}}{\partial x}^T \vec{v} + \frac{\partial \vec{v}}{\partial x}^T \vec{u}.$$

$$\frac{\partial A \vec{u}}{\partial x} = \frac{\partial \vec{u}}{\partial x} A^T.$$

$$\mathcal{N}(\mu, \Sigma): \frac{1}{(2\pi)^{d/2} |\Sigma|^{1/2}} \exp\left(-\frac{1}{2}(x - \mu)^T \Sigma^{-1} (x - \mu)\right).$$
